# Cryptococcal meningitis

---

Cryptococcal meningitis is a serious infection that affects the lungs or the central nervous system. It is caused by a fungus called *Cryptococcus neoformans*. It can occur in people with people who have weakened immune systems, particularly those living with an advanced stage of HIV.

*Cryptococcus neoformans* is very common in the environment and can be found in soil and in bird droppings. If that soil is kicked up into the air, it can be inhaled into the lungs. From there, the fungus can travel through the blood to the spinal column and brain where it can cause disease. While most adults and children have been exposed to this fungus at some point during their lives, they generally have immune systems that are healthy enough to prevent the disease.

Cryptococcal meningitis results in inflammation and swelling of the brain, which can be extremely debilitating and painful and cause damage to the brain. Cryptococcal meningitis can be fatal if not treated.

What are the symptoms, and how is it diagnosed?

Many of the symptoms are similar to those seen in other illnesses, including cough, fever, shortness of breath and chest pain. Other symptoms may include headache, neck pain, nausea and vomiting, sensitivity to light, confusion or changes in behavior.

It is very important for people living with HIV at lower CD4 counts to monitor their health closely and report any symptoms to their health care provider.

Your doctor will send a sample of tissue or body fluid to a laboratory for examination. Some doctors also request a chest x-ray or CT scan of your lungs, brain or other parts of your body.

How is it treated?

Treatment for cryptococcal meningitis depends on the severity of the infection and which parts of the body are affected. Antifungal treatment, such as fluconazole, is generally prescribed for mild to moderate pulmonary infections.

A combination of amphotericin B and flucytosine is the recommended initial treatment for people who have severe infection in the lungs or central nervous system. Following that, an extended treatment of fluconazole is prescribed to clear the infection.

How is it prevented?

Because *Cryptococcus neoformans* can be found in many parts of the environment, it is very difficult to prevent coming into contact with it. Moreover, the fungus can live in a person's body for many months or possibly years before it causes disease, depending on the health of the person's immune system.

Since the fungus will most likely lead to cryptococcal meningitis in people with low CD4 counts, the best possible way to prevent this disease is to keep the immune system as healthy as possible. This includes starting HIV treatment before the immune system weakens.
